running. Exploratory round 1 done 2026-10-03: HH77 partially supported (one Curie–Weiss-like market mode, partly joint lulls); HH58 refuted in direction (kickoffs expand dimensionality; self-repetition, not consensus, collapses it). Confirmatory script writ...

WHAT HAPPENED

Not yet summarized. The question: How many collective modes does the swarm have beyond random-matrix noise, and does the effective dimensionality of what agents say collapse after kickoffs and during consensus, then re-expand in free weeks? Practical payoff: a cheap, model-free monitor of whether a swarm is 'thinking alike'.

PHYSICAL MODEL

From: physics-models/01-inverse-ising and physics-models/11-vector-spins with random-matrix theory: Marchenko–Pastur edges for $N \times T$ correlation matrices (activity or talk spins per minute; content time series per window), and the participation ratio $PR = (\sum \lambda)^2 / \sum \lambda^2$ of the swarm's whitened embedding covariance per window. The top mode is compared with H02's Curie–Weiss collective co-activation. - Model 01 reading. For e
