

H19 · One curve for all periods? Loop-gain data collapse across 35 goal periods (exploratory round 1)

P1 FAILED. No common curve: on x_{att} the equal-time active-spin gains rise (g_{eq} slope $+0.13$ [$+0.06, +0.20$], R^2_{het} 0.41) while the Hawkes talk gains fall (fast n_x slope -0.06 [$-0.10, -0.02$]); regime-only beats the collapse by 11.5 nats (LOPO). The methods split by spin CHANNEL, not by estimator family: talk-based gains (H03 n_x , H04 n_x , g_{eq} talk) agree with each other (ρ 0.4-0.7) and with the derived Hawkes-to-Ising mapping (P3, ρ 0.44); activity-spin gains form a separate cluster (g_{eq} active vs H04 K ρ 0.94) unrelated to them. Post hoc: k_{llm} (messages delivered per LLM step) collapses all 5 talk-channel gains with one sign ($+25$ nats vs regime-only) -- a round-2 candidate, not a result. Synthetic: false 'supported' $\leq 1\%$ under every rival; power 0.87 at $R^2=0.5$.

Collapse plot: every method z-scored, with its own meta-regression line on x_{att} (bold = primaries T1, E1)

Outcome vs. prediction

Prediction	Outcome
P1 collapse on x_{att}	failed
P2 concordance, equal-time	failed
P2 concordance, Hawkes	supported
P3 cross-family mapping	supported
P4 dilution exponent	failed
P5 no mode effect	supported

Collapse model vs. rivals (> 2 needed)

Synthetic validation: share of data sets the P1 rule calls supported / mixed, by true generating model
