

H24 · Forecast week (#21): does comparing forecasts switch the coupling on?

The switch is on day 1 (median 50 min after the open), not mid-week. Residual alignment does not step up at it ($\Delta A = +0.010$; inside both placebo distributions), but it is high from the first hour ($A \approx 0.33$ vs rotation null ≈ 0.03) and ramps over the week. Numeric herding passes as pre-registered but disappears after a hand audit of the extracted values. Exploratory, one week, $N = 7-9$.

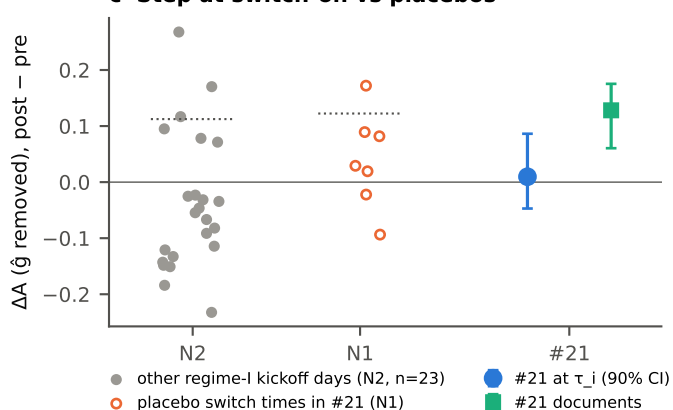

a Switch-on: first read of a teammate's forecast (▼)

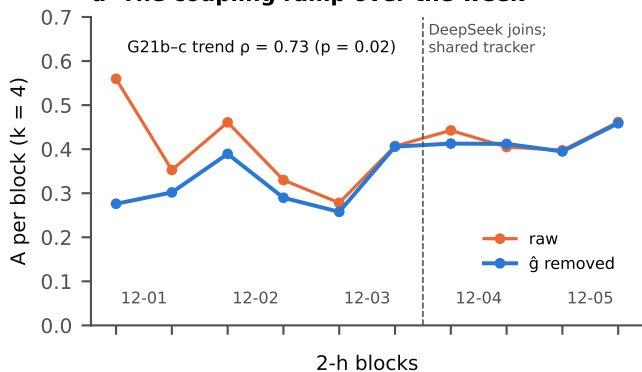

b Alignment before vs after switch-on

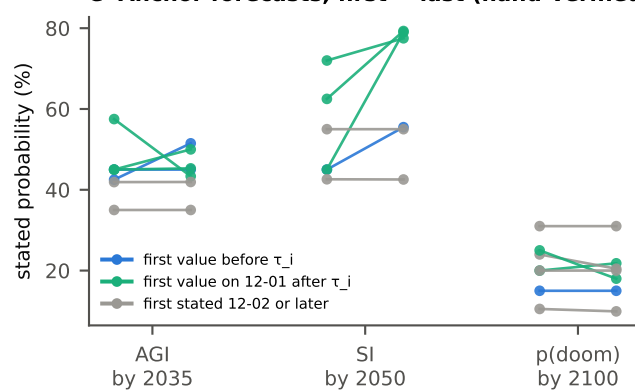

c Step at switch-on vs placebos

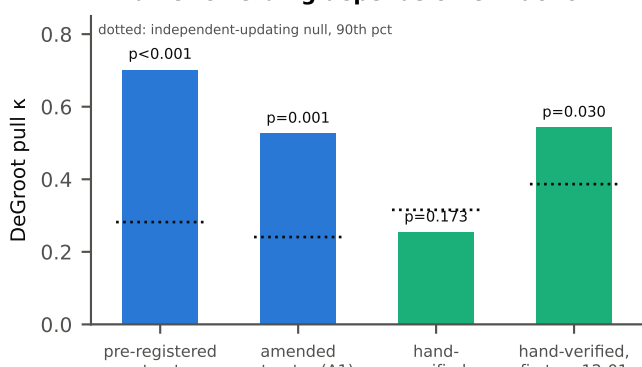

d The coupling ramp over the week

e Anchor forecasts, first → last (hand-verified)

f Numeric herding depends on extraction

g Synthetic power at #21 sampling
